

Hospital Appointment Management System

Lean Workflow

Feature: Appointment reminders

Step 1 and 2: Activities and classification.

Customer value: Comes from meeting receptionists and patients to understand what they need, designing the reminder message and delivery timing, building the scheduler that sends reminders automatically, demonstrating the feature to users and collecting their feedback, fixing bugs and making improvements based on what we learn, and deploying the feature so patients can actually benefit from it.

Necessary support: Includes writing the user story and acceptance criteria, setting up the SMS and email service, testing that reminders send on time to the correct patients, and holding review meetings with the team to keep quality high and everyone aligned.

Waste: Consists of writing detailed documentation of every meeting and decision that no one reads, waiting for approval from every team member before starting each next task, which slows delivery down.

Step 3: Kanban workflow

BACKLOG: Reminder frequency options, reminder in local

READY: Design reminder message, set up SMS/email service

DOING: Build the scheduler

TESTING: Test reminder timing, test correct patient receives it.

REVIEW: Team review of scheduler

DONE: Write user story, meet receptionist and patients

Step 4: Activities to eliminate or improve

Heavy documentation of every detail, waiting for approval from every team member and manually testing every reminder scenario.

Step 5: How removing those activities improves efficiency

Less documentation frees up time for actual building and testing. Short, focused notes are easier to keep accurate, since long documents tend to go outdated and get ignored. No waiting for full

team approval keeps work moving. Tasks finish faster and the team gets feedback sooner instead of losing days to approval delays.
